1 Single Layer Classifier

1.1 Observation and Analysis

- Bias is an important factor as it can boost the performance by a good margin.

- Hyperparameter tuning:
    - Best Epoch Size = 10
    - Best Batch Size = 64

- Though our Test accuracy is comparatively less, it can be significantly boosted by increasing the layers.

- Test Accuracy: 73.43 %

- Linear Classifier of Scikit Learn has a better accuracy of 92.4 % on the test dataset.

- Best Performing Class: 0 (Checked on the whole test dataset).

- Training Accuracy plot:
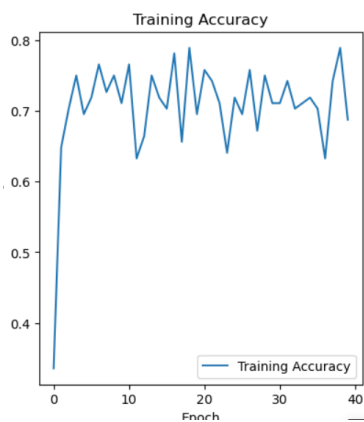

2 Scalar Backpropagation
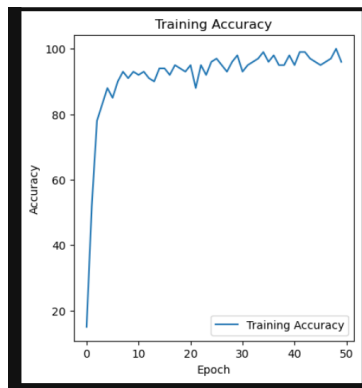

2.1 Observations and Analysis

- We are calculating the gradient of the final function value with respect to all the sub-function elements.

- Example results:

```
For x: 2 , y: 4 , z: 1
Grad x :0.284 , Grad_y :0.204 , Grad_z:-0.131
For x: 9 , y: 14 , z: 3
Grad x :-0.824 , Grad_y :0.273 , Grad_z:0.0197
For x: 128 , y: 42 , z: 666
Grad x :-7.204e-16 , Grad_y :-3.99e-16 , Grad_z:0.0
For x: 52 , y: 14 , z: 8
Grad x :8.763e-16 , Grad_y :-1.214e-16 , Grad_z:-3.998e-22
```

3 Modular Vector Backpropagation

3.1 Observations and Analysis

- Mean accuracy has increased in this case for the same MNIST dataset.

- Accuracy is a bit on the higher side, most probably the model is overfitting and regularization is needed.

- In the hidden layers, we are using ReLU. ReLU and its derivative both being simple to calculate make the computation easy.

- Here also we are using a cross-entropy loss because we are using softmax activation, which goes better with multi-class classification.
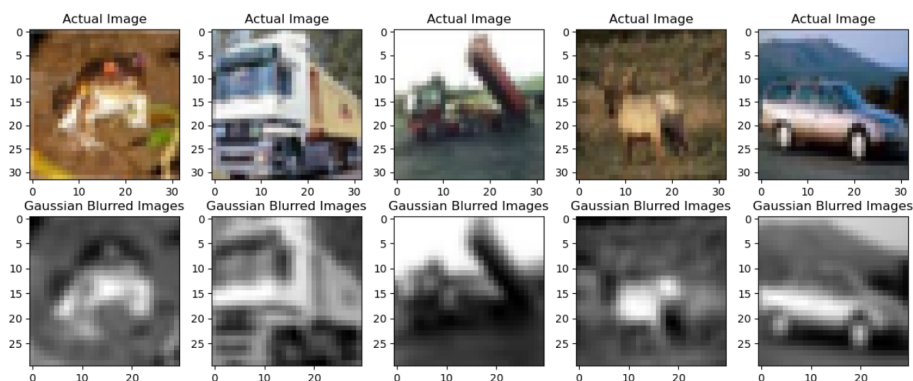

- Training Accuracy plot:

4 Convolution Module with Numpy

4.1 Observations and Analysis

- This is the Gaussian blur filter.
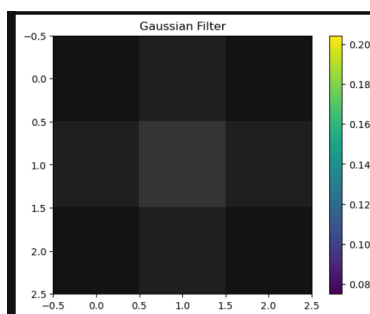

- Tried this question with a custom box filter also but using a Gaussian filter keeps the image a bit smooth and preserves a bit more details.

- Side by Side Comparison of actual image and gaussian blurred image

5 Training a Convolution Layer

5.1 Observation and Analysis

- The L2 distance between C and C_0 is 5661470.045074505.
